
interpreter-bound: time per Python / NumPy call, not flops

dense LU, moderate size: 60 GFLOP/s on one core (BLAS-3)

dense nonsymmetric eigensolver: dominant (88% of a convergence row), threads help little (×2.11 on 4)

Parallel width: shooting: candidate amplitudes independent | continuation: none (each step needs the last) |
spectra: every branch point, grid and absorber independent | split-step: noise realizations independent

Used in the production runs: BLAS threads only, inside one Python process.
